

Exercise 1.4

There is a code in php language:

```
<?php foreach ([1,2,3] as $i) {echo $i . PHP_EOL;}
```

Copy this code to a file counter.php. (Or you can use the file that I attached to the task.)

Then download two images:

```
docker pull php:5.3-cli
```

```
docker pull php:5.6-cli
```

Then run the code on php in both containers and check how it works?

For one of the containers, it will fail – this is expected.

To run the code in php use command:

```
php counter.php
```

Submit a pdf or a Word file with three answers

and

with a picture of the console after you ran a container with version 5.6:

1. Which type of mount did you choose? Why?
2. What was the output of the code when running within container with version 5.3?
3. What was the output of the code when running within container with version 5.6?
